

Data Modeling using Entity Relationship (E-R) Diagram

Overview of Database

Two main activities:

- Database design :To design the conceptual schema for a database application
- Applications design: The design focuses on the programs and interfaces that access the database

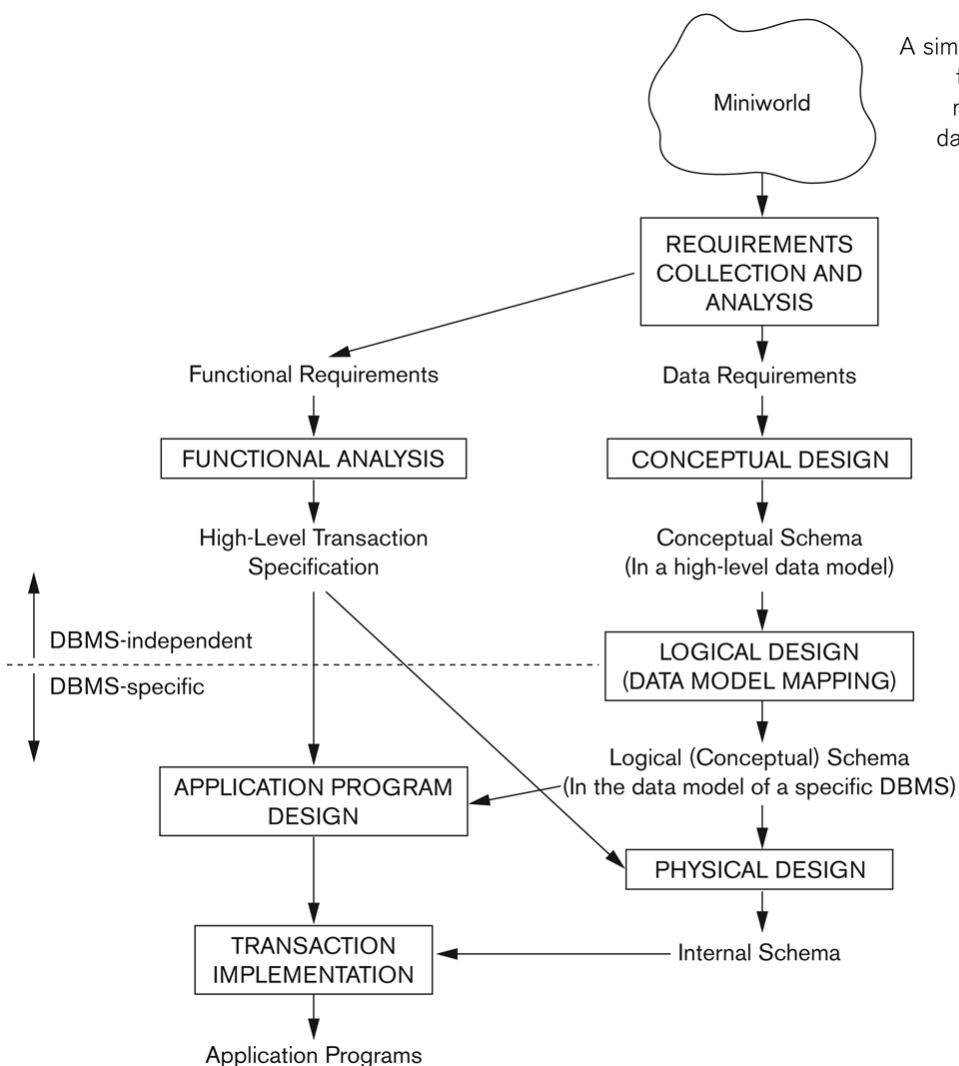

Figure 3.1

A simplified diagram to illustrate the main phases of database design.

Entity-Relationship (ER) Model Concepts

- A popular high-level conceptual data model
- Entities and Attributes

Entities are specific objects or things in the mini-world that are represented in the database.

For example the EMPLOYEE John Smith, the Research DEPARTMENT, the ProductX PROJECT

Attributes are properties used to describe an entity.

For example an EMPLOYEE entity may have the attributes Name, SSN, Address, Gender, BirthDate

- A specific entity will have a value for each of its attributes.

For example a specific employee entity may have Name='John Smith', SSN='123456789', Address ='731, Fondren, Houston, TX', Gender='M', BirthDate='09-JAN-55'

Each attribute has a *value set* (or data type) associated with it – e.g. integer, string, subrange, enumerated type, etc

Types of Attributes

1. Simple

Each entity has a single atomic value for the attribute. For example, SSN or Gender.

2. Composite

The attribute may be composed of several components.

For example: Address(Apt#, House#, Street, City, State, ZipCode, Country), or Name(FirstName, MiddleName, LastName).

Composition may form a hierarchy where some components are themselves composite.

3. Multi-valued

An entity may have multiple values for that attribute.

For example, Color of a CAR or PreviousDegrees of a STUDENT.

Denoted as {Color} or {PreviousDegrees}.

Example of a Composite Attribute

Figure 3.4

A hierarchy of composite attributes.

In general, **composite and multi-valued attributes may be nested arbitrarily to any number of levels**, although this is rare.

- For example, PreviousDegrees of a STUDENT is a composite multi-valued attribute denoted by {PreviousDegrees (College, Year, Degree, Field)}
- Multiple PreviousDegrees values can exist
- Each has four subcomponent attributes:
- College, Year, Degree, Field

4. Complex Attributes

Nested composite and multivalued attributes

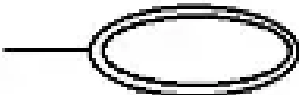

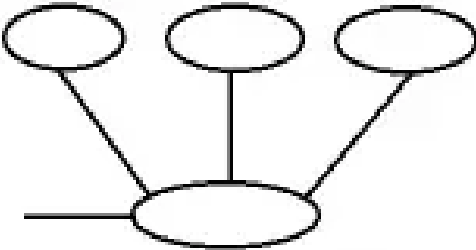

Ex. A person has more than one residence and each residence can have a single address and multiple phones.

5.Stored and Derived Attributes

An derived attribute is derived from a stored attribute

Ex. We can derive a man’s age from his birthday.

Notations Of Attributes in ER Diagram

	Attribute
	Key Attribute
	Multivalued Attribute
	Compound/Composite Attribute
	Derived Attribute

Null Values -

Its meaning includes

- An attribute value is not applicable
- An attribute value is unknown
- The value exists but is missing
- The value is unknown whether it exists

Entity Types and Key Attributes

Entities with the same basic attributes are **grouped** or typed into an entity type.

For example, the entity type EMPLOYEE and PROJECT.

- An attribute of an entity type for which each entity must have a unique value is called a **key attribute** of the entity type.
For example, SSN of EMPLOYEE.
A key attribute may be composite.
VehicleTagNumber is a key of the CAR entity type with components (Number, State).
- An entity type may have more than one key.
The CAR entity type may have two keys:

VehicleIdentificationNumber (popularly called VIN)
 VehicleTagNumber (Number, State), aka license plate number.

Displaying an Entity Type

- In ER diagrams, an entity type is displayed in a rectangular box
- Attributes are displayed in ovals
- Each attribute is connected to its entity type
- Components of a composite attribute are connected to the oval representing the composite attribute
- Derived attributes are denoted by dotted ovals
- Each key attribute is underlined
- Multivalued attributes displayed in double ovals

See CAR example below

Entity Type CAR with two keys and a corresponding Entity Set

(a)

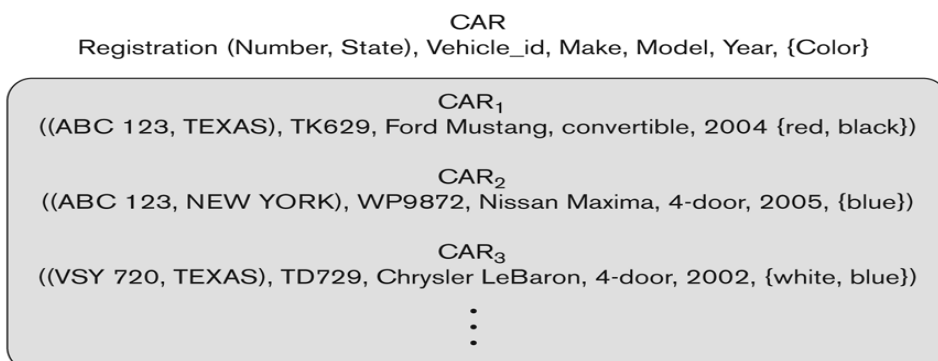

Figure 3.7

The CAR entity type with two key attributes, Registration and Vehicle_id. (a) ER diagram notation. (b) Entity set with three entities.

(b)

Entity Set Value Sets (Domains) of Attributes

Each entity type will have a collection of entities stored in the database called the **entity set** (also called the **extension** of the entity type)

An entity type describes the **schema** or **intension** for a set of entities.

- Ex: Three CAR entity instances in the entity set for CAR. Same name (CAR) used to refer to both the entity type and the entity set.

Entity set is the current *state* of the entities of that type that are stored in the database. Each simple attribute is associated with a **value set** (or **domain** of values) .

- Ex. The **Age** attribute of **EMPLOYEE** to be the set of integer numbers between 16 to 70

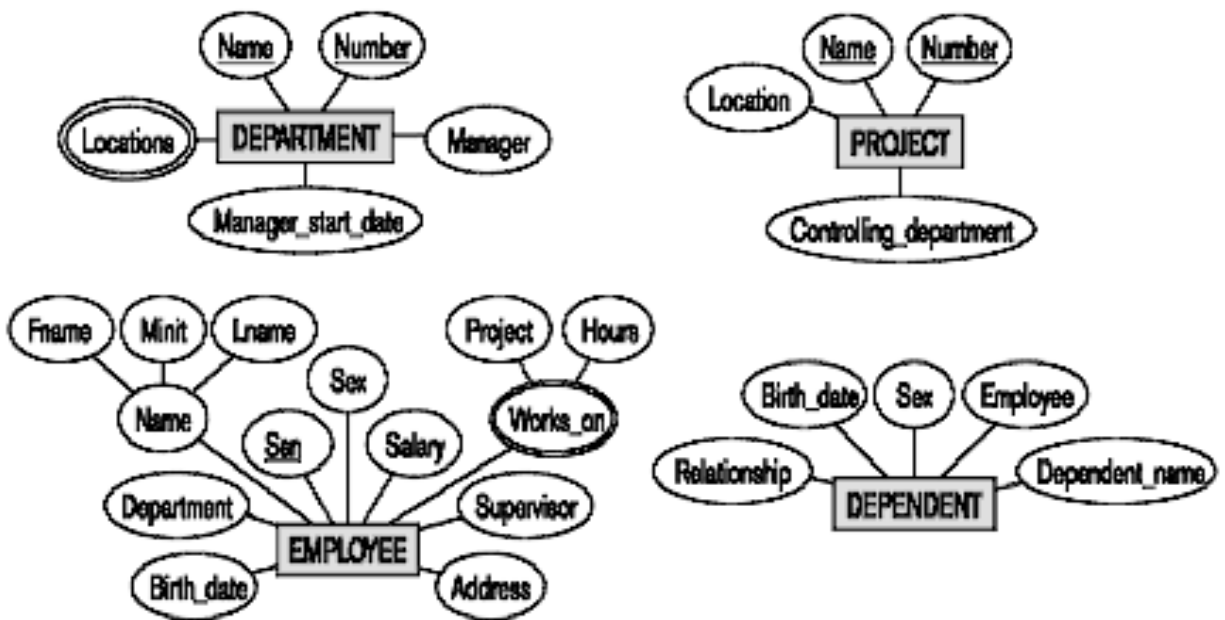

Initial Design of Entity Types for the COMPANY Database Schema

Based on the requirements, we can identify four initial entity types in the COMPANY database:

- DEPARTMENT
- PROJECT
- EMPLOYEE
- DEPENDENT

Initial Design of Entity Types:

EMPLOYEE, DEPARTMENT, PROJECT, DEPENDENT

Refining the Initial Design by Introducing Relationships

The initial design is typically not complete. Some aspects in the requirements will be represented as **relationships**

ER model has **three** main concepts:

- Entities (and their entity types and entity sets)
- Attributes (simple, composite, multivalued)
- Relationships (and their relationship types and relationship sets)

Relationships and Relationship Types

A **relationship** relates two or more distinct entities with a specific meaning.

- For example, EMPLOYEE John Smith *works on* the ProductX PROJECT, or EMPLOYEE Franklin Wong *manages* the Research DEPARTMENT.

Relationships of the same type are grouped or typed into a **relationship type**.

- For example, the WORKS_ON relationship type in which EMPLOYEEs and PROJECTs participate, or the MANAGES relationship type in which EMPLOYEEs and

DEPARTMENTS participate.

The degree of a relationship type is the number of participating entity types.

- Both MANAGES and WORKS_ON are *binary* relationships.

Relationship Instances of the WORKS_FOR N:1

Relationship between EMPLOYEE and DEPARTMENT

Relationship Instances of the M:N WORKS_ON

Relationship between EMPLOYEE and PROJECT

Relationship Type vs. Relationship Set

Relationship Type:

- Is the schema description of a relationship
- Identifies the relationship name and the participating entity types
- Also identifies certain relationship constraints

Relationship Set:

- The current set of relationship instances represented in the database
- The current *state* of a relationship type

In ER diagrams, we represent the *relationship type* as follows:

- Diamond-shaped box is used to display a relationship type
- Connected to the participating entity types via straight lines

Refining the COMPANY Database Schema by Introducing Relationships

By examining the requirements, six relationship types are identified

All are *binary* relationships (degree 2)

Listed below with their participating entity types:

- WORKS_FOR (between EMPLOYEE, DEPARTMENT)
- MANAGES (also between EMPLOYEE, DEPARTMENT)
- CONTROLS (between DEPARTMENT, PROJECT)
- WORKS_ON (between EMPLOYEE, PROJECT)
- SUPERVISION (between EMPLOYEE (as subordinate), EMPLOYEE (as supervisor))
- DEPENDENTS_OF (between EMPLOYEE, DEPENDENT)

Discussion on Relationship Types

In the refined design, some attributes from the initial entity types are refined into relationships:

- Manager of DEPARTMENT -> MANAGES
- Works_on of EMPLOYEE -> WORKS_ON
- Department of EMPLOYEE -> WORKS_FOR etc

In general, more than one relationship type can exist between the same participating entity types

- MANAGES and WORKS_FOR are distinct relationship types between EMPLOYEE and DEPARTMENT
- Different meanings and different relationship instances.

Each entity type that participates in a relationship type plays a particular **role** in the relationship

Recursive Relationship Type

A relationship type where the same entity type participates more than once in the relationship in **distinct roles** is called **recursive relationship**

Example: the SUPERVISION relationship

- EMPLOYEE participates twice in two distinct roles:
 - supervisor (or boss) role
 - supervisee (or subordinate) role
- Each relationship instance relates two distinct EMPLOYEE entities:
 - One employee in *supervisor* role
 - One employee in *supervisee* role

Displaying a Recursive Relationship

- In a recursive relationship type.
- Both participations are same entity type in different roles.
- For example, SUPERVISION relationships between EMPLOYEE (in role of supervisor or boss) and (another) EMPLOYEE (in role of subordinate or worker).
- In following figure, first role participation labeled with 1 and second role participation labeled with 2.
- In ER diagram, need to display role names to distinguish participations.

A Recursive Relationship Supervision

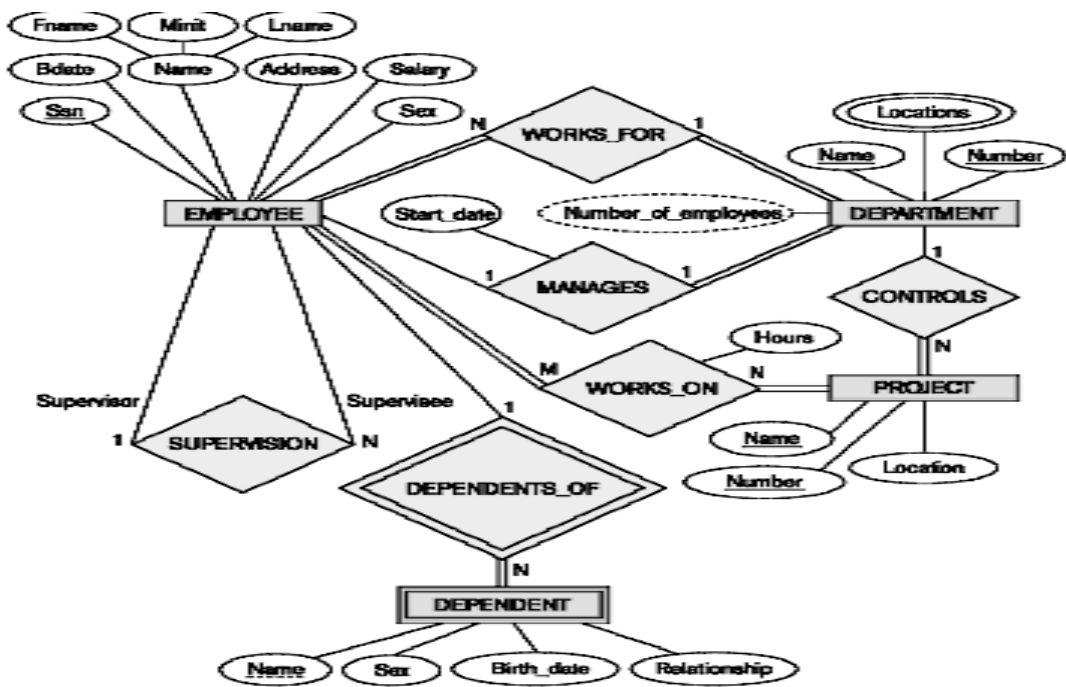

Figure 3.11
A recursive relationship SUPERVISION between EMPLOYEE in the *supervisor* role (1) and EMPLOYEE in the *subordinate* role (2).

Recursive Relationship type is : SUPERVISION (participation role names are shown)

Weak Entity Types

An entity that does not have a key attribute

A weak entity must participate in an identifying relationship type with an owner or identifying entity type

Entities are identified by the combination of:

A partial key of the weak entity type

The particular entity they are related to in the identifying entity type

Example:

A DEPENDENT entity is identified by the dependent's first name, *and* the specific EMPLOYEE with whom the dependent is related

- Name of DEPENDENT is the *partial key*
- DEPENDENT is a *weak entity type*
- EMPLOYEE is its identifying entity type via the identifying relationship type DEPENDENT_OF
- A weak entity type and its identifying relationship are distinguished by surrounding their boxes and diamonds with double lines
- The partial key attribute is underlined with a dashed or dotted line

Constraints on Relationships

Constraints on Relationship Types:

1. Cardinality Ratio (specifies **maximum** participation)
 - i. One-to-one (1:1)
 - ii. One-to-many (1:N) or Many-to-one (N:1)
 - iii. Many-to-many (M:N)
2. Existence Dependency Constraint (specifies **minimum** participation) (also called participation constraint)
 - i. zero (optional participation, not existence- dependent)
 - ii. one or more (mandatory participation, existence-dependent)

Many-to-One (N:1) Relationship

Figure 3.13
An M:N relationship,
WORKS_ON.

Many-to-Many (M:N) Relationship

Figure 3.13
An M:N relationship,
WORKS_ON.

Attributes of Relationship Types

A relationship type can have attributes:
For example, HoursPerWeek of WORKS_ON. Its value for each relationship instance describes the number of hours per week that an EMPLOYEE works on a PROJECT. A value of HoursPerWeek depends on a particular (employee, project) combination

- Most relationship attributes are used with M:N relationships. For M:N relationships, some attributes are determined by the combination of participating entities, not by a single entity. Such attributes must be specified as relationship attributes
- In 1:1 relationships, they can be transferred to one of the participating entities
- In 1:N relationships, they can be transferred to the entity type on the N-side of the relationship
- The decision as to where a relationship attribute should be placed is determined subjectively by the schema designers

Example Attribute of a Relationship Type: Hours of WORKS_ON

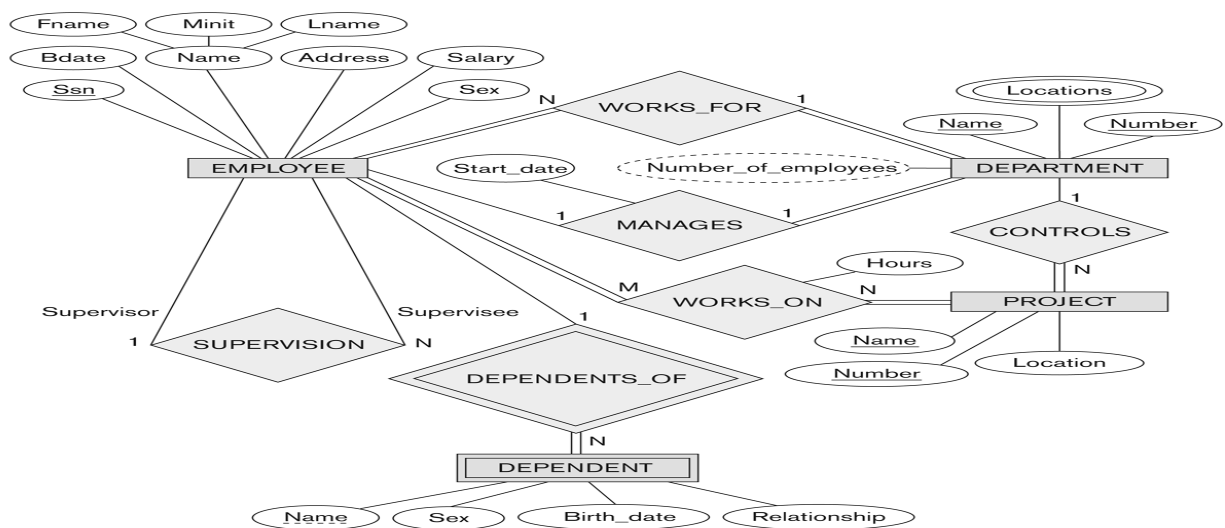

Figure 3.2
An ER schema diagram for the COMPANY database. The diagrammatic notation is introduced gradually throughout this chapter.

Notation for Constraints on Relationships

- Cardinality ratio (of a binary relationship): 1:1, 1:N, N:1, or M:N
- Shown by placing appropriate numbers on the relationship edges.
- Participation constraint (on each participating entity type): **total** (called existence dependency) or **partial**.
- Total shown by double line, partial by single line.
- NOTE: These are easy to specify for Binary Relationship Types.
- Structural Constraints = Cardinality Ratio Constraints + Participation Constraints

Alternative (min, max) Notation for Relationship Structural Constraints

- Specified on each participation of an entity type E in a relationship type R
- Specifies that each entity e in E participates in at least *min* and at most *max* relationship instances in R
- Default (no constraint): min=0, max=n (signifying no limit)
- Must have min≤max, min≥0, max ≥1
- min=0 implies partial participation; min>0 implies total participation
- Derived from the knowledge of mini-world constraints

Examples:

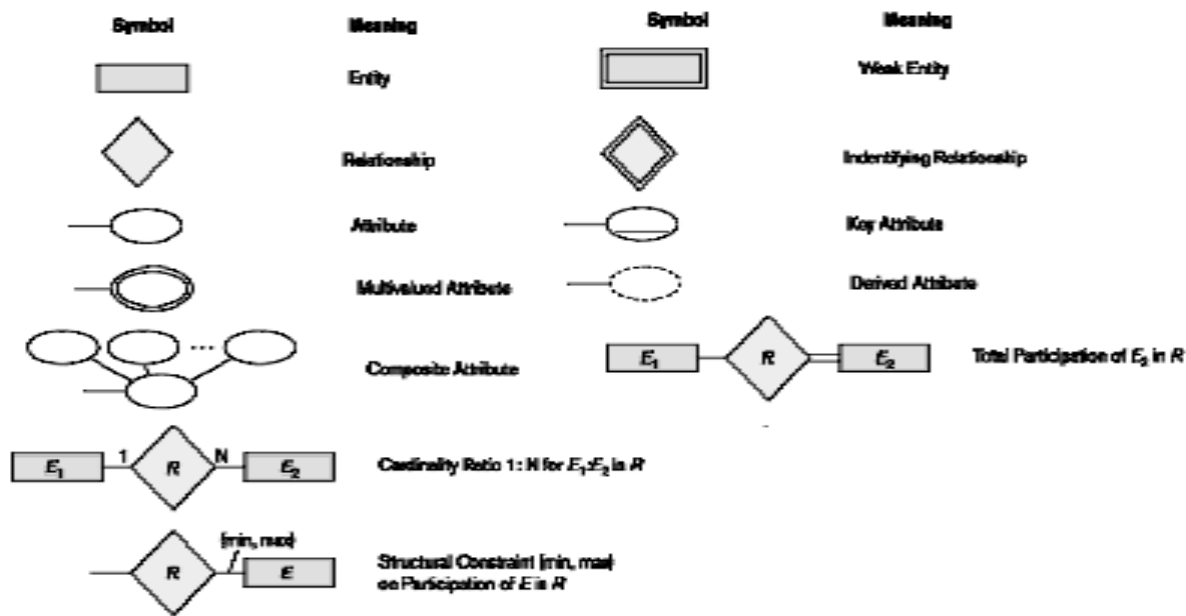

- A department has exactly one manager and an employee can manage at most one department.
- Specify (1,1) for participation of DEPARTMENT in MANAGES
- Specify (0,1) for participation of EMPLOYEE in MANAGES
- An employee can work for exactly one department but a department can have any number of employees.
- Specify (1,1) for participation of EMPLOYEE in WORKS_FOR
- Specify (1,n) for participation of DEPARTMENT in WORKS_FOR

The (min,max) Notation for Relationship Constraints

- Read the min,max numbers next to the entity type and looking away from the entity type

Summary of Notation for ER Diagrams

COMPANY ER Schema Diagram Using (min, max) Notation
